Distributed Computer Systems – Laboratory 1

Introduction to java.net module

1. Compile and run the program delivered by the lecturer.
2. Modify the program so it would take the hostname or address for connecting as the execution argument (hint: use the **`args`** array).
3. Try to check if the program is able to connect to remote hosts.
4. Add functionality to the program for reading the canonical host name, the hashcode of the IP address, and checking if the provided address is multicast.
5. Modify the program so it would try to connect the remote host by its IP address, not the name (hint: use the **`getByAddress()`** method).
6. Write the program that will check for a range of addresses inside the provided network address to see if the provided hosts exist (hint: use the **`isReachable()`** method).
